Buyer Assurance

All bulls offered for sale in this catalogue have passed the following Quality Assurance measures:

- ☑ Independent Vet Inspection for structural & reproductive soundness.
- ☑ Semen Test to meet Australian Cattle Veterinarians Standard for natural service. Test results are available for inspection from the vendors or at the agents' office in the Sales Complex.
- ☑ Tested PI negative.
- ☑ Vendors Guarantee.
- ☑ All bulls catalogued have been sire verified using DNA and have been tested free from all known genetic conditions..

Explanatory Notes for Horned Status of Animals

Please note that as per the Regulations of Herefords Australia Ltd.

“Description of Animals”

Polled, Horned, Scurred or H# animals shall be eligible for registration; and the letter P, H, S or H# shall be shown in the Company's records and on the Registration Certificate, as the recorded phenotype as provided by the breeder at the time of registration.

Any animal that has been DNA tested for Poll/Horn status and is found to be homozygous polled will automatically receive PP as a horn status:

(PP) – Homozygous Polled

(The animal has been DNA tested and the test result indicates that it is Homozygous Polled)

(P) – Polled

(H) – Horned

(S) – Scurred

(H#) – is a Horned animal either containing Polled genetics OR is missing a percentage of its four generation Horned pedigree

Any lots that have been tested for their Poll Gene Marker have their results printed in the catalogue. The results will show whether the bull is Homozygous (PP) or Heterozygous (PH) Polled.

A Homozygous Polled (PP) animal is a 'True Polled' animal and will only produce Polled (or Scurred) calves. They will not produce Horned calves.

A Heterozygous Polled (PH) animal carries a Polled and Horned gene and can produce Polled, Horned (or Scurred) calves.

Johne's Beef Assurance Score (J-BAS)

J-BAS is a risk profiling tool developed for use in the new approach to Johne's disease (JD) in beef cattle. The scoring system is from 0 (being 'Unmanaged risk') to 8 ('High Assurance'). Vendors of the Show and Sale are required to have a minimum of a J-BAS 6 in order to exhibit at the event. For more information please go to www.animalhealthaustralia.com.au

It is the responsibility of all potential purchasers to conduct their own due diligence regarding the Johnes disease status of the lots that they are interested in purchasing.

Herefords Australia Ltd and the Herefords Australia National Show and Sale (Dubbo) Management Committee take no responsibility for the J-BAS status of any of the listed herds or cattle.

Sire Verification and Genetic Conditions

All bulls catalogued have been sire verified using DNA and have been tested free from all known genetic conditions.

GET YOUR CATTLE PERFORMANCE READY WITH MULTIMIN

Multimin Injection makes your cattle 'performance ready' by boosting immunity and fertility. Applied four weeks before joining, Multimin rapidly 'tops up' levels of essential trace minerals required for conception and embryo survival. Scientific studies conducted in Australia and throughout the world have shown that Multimin can improve early conception rates in females¹ and sperm quality in bulls².

Effect of Multimin on conception at first cycle¹

1. Virbac trial protocol No. 578-15.
2. Ferreira et al. (2016), WBC. Dublin. Benefits outlined in these scientific studies are not registered label claims.

Breedplan made easy

Breedplan is a performance evaluation program that compares bulls “on a level playing field” for a number of important commercial traits.

The difference between a bull's genetics and the breed benchmark for a range of traits is reported as an **Estimated Breeding Value (EBV)** – an estimate of how a bull will perform as a parent rather than how he looks on the day.

EBVs can be positive (+) or negative (-), ie, above or below the breed benchmark of zero.

EBVs are calculated from the available performance information on the animal, its parents, progeny and its close relatives within the breed.

The information is adjusted for age, dam age, and for differences between herds, years, season of calving, management effects and for mating and selection biases. The heritability of the trait is also taken into account.

EBVs – what do they tell me about a bull

BIRTH

Birth Weight: The Birth Weight EBV (kg) is based on the measured birth weight of animals, adjusted for dam age. The lower the value the lighter the calf at birth and the lower the likelihood of a difficult birth. This is particularly important when selecting sires for use over heifers.

FERTILITY

Scrotal Size: The Scrotal Size EBV (cm) is an indicator of male fertility. Higher (positive) EBVs indicate higher fertility. Higher SS EBVs are also positively associated with female fertility through earlier age of puberty.

GROWTH

Milk: 200-Day Milk EBV (kg) is an estimate of the contribution that a dam makes to the 200 day weight of her progeny. For sires, this is an indication of the contribution that his daughters will make to the 200 day weight of their calves.

200-Day Growth: The 200-Day EBV (kg) is calculated from the weight of animals taken between 80 and 300 days of age. Values are adjusted to 200 days and for dam age. This EBV is the best single estimate of an animal's genetic merit for growth to early ages (ie. 8-10 months).

400-Day Weight: The 400-Day Weight EBV (kg) is calculated from the weight of progeny taken between 301 and 500 days of age, adjusted to 400 days and for dam age. This EBV is the best single estimate of an animal's genetic merit for yearling weight.

600-Day Weight: The 600-Day Weight EBV (kg) is calculated from the weight of progeny taken between 501 and 900 days of age, adjusted to 600 days and for dam age. This EBV is the best single estimate of an animal's genetic merit for growth beyond yearling age.

CARCASE

Eye Muscle Area: The EMA EBV (cm²) estimates genetic differences in eye muscle area at the 12/13th rib site of a 300kg dressed carcass. More positive EBVs indicate better muscling on animals.

Rib Fat: The Rib Fat EBV (mm) estimates the genetic differences in fat depth at the 12/13th rib in a 300kg dressed carcass. More positive EBVs indicate more subcutaneous fat and earlier maturity.

Rump Fat: The Rump Fat EBV (mm) estimates the genetic differences in fat depth at the P8 site of a 300kg dressed carcass. More positive EBVs indicate more subcutaneous fat and earlier maturity.

Intramuscular Fat Percent: The IMF% EBV (%) is an estimate of the genetic difference in the percentage of intra-muscular fat at the 12/13th rib site in a 300kg carcass. More positive EBVs indicate higher marbling.

EBVs on sale cards displayed on sale day may vary from those published in this catalogue.

Hereford group breedplan data:

1. Minimum Requirements

Bulls appearing in this catalogue are required to have current reportable Group Breedplan EBV's for 200, 400 and 600 day weights, fat depth (rib and rump), eye muscle area and intramuscular fat.

2. Traits Observed

The Breedplan data for each lot in this catalogue carries a “Traits Observed” indicator. This identifies those traits for which the animal has been directly measured and the animal's measurement has been included in the BREEDPLAN analysis. Where an animal has not been observed for a trait, the EBVs have been calculated from measurements on other related traits and the performance of the animal's relatives.

Breedplan accuracy

What is Accuracy?

By definition, an EBV is an estimate of an animal's true breeding value. The "accuracy" figure produced with each EBV provides a measure of the stability of the EBV and gives an indication of the amount of information that has been used in the calculation of that EBV. The higher the accuracy the lower the likelihood of change in the animal's EBV as more information is analysed for that animal, its progeny or its relatives.

Accuracy figures are reported as a percentage (%) between 0 – 99, with higher accuracy values indicating that more information has been used in the calculation of the EBV than a lower accuracy value.

How do I interpret Accuracy?

The following guide may be useful for interpreting accuracy:

Less than 50% accuracy - the EBVs are preliminary. EBVs in this range will have been calculated based on very little information. These EBVs could change substantially as more direct performance information becomes available on the animal.

50-74% accuracy - the EBVs are of medium accuracy. EBVs in this range will usually have been calculated based on the animal's own performance and some limited pedigree information.

75-90% accuracy - the EBVs are of medium-high accuracy. EBVs in this range will usually have been calculated based on the animal's own performance coupled with the performance for a small number of the animal's progeny.

More than 90% accuracy - the EBVs are a high accuracy estimate of the animal's true breeding value. It is unlikely that EBVs will change considerably with addition of more progeny data.

Although the accuracy of an EBV should be considered, animals should be compared on EBVs regardless of accuracy. Where two animals have the same EBV however, the animal with the higher accuracy would normally be used more heavily than the bull with the lower accuracy because the results can be predicted with more confidence.

Remember, all information that is known about an animal and its relatives is considered in the calculation of its EBVs. Subsequently, the EBV will be the best estimate available of an animal's genetic merit, regardless of accuracy.

TRAITS OBSERVED:

Identifies those traits for which the animal has been directly measured and the animal's measurement has been included in the BREEDPLAN analysis.

Hereford selection indexes

There are currently four different selection indexes calculated for Australian Hereford animals. These are:

- Supermarket Index
- Grass Fed Steer Index
- Grain Fed Steer Index
- EU Index

Each selection index describes a different production/market scenario and relates to a typical, self replacing Hereford herd in temperate Australia targeting the following specifications.

Supermarket Index – Estimates the genetic differences between animals in net profitability per cow joined for an example commercial herd targeting the domestic supermarket trade. Steers are either finished on grass or grain (eg. 50 – 70 days). Steers are assumed marketed at 450kg live weight (250kg HSCW and 12mm P8 fat depth) at 17 months of age. Daughters are retained for breeding. In response to industry feedback regarding eating quality and tenderness, a small premium has been placed on marbling.

Grass Fed Steer Index – Estimates the genetic differences between animals in net profitability per cow joined for an example commercial herd targeting pasture finished steers. Steers are assumed marketed at 600kg live weight (33kg HSCW and 8 mm P8 fat depth) at 23 months of age. Daughters are retained for breeding. In response to industry feedback regarding eating quality and tenderness, a small premium has been placed on marbling.

Grain Fed Steer Index – Estimates the genetic differences between animals in net profitability per cow joined for an example commercial herd targeting pasture grown steers with a 125 day feedlot finishing period for the grain fed markets. Steers are assumed marketed at 600kg live weight (330kg HSCW and 20mm P8 fat depth) at 20 months of age. Daughters are retained for breeding. There is a significant premium if steers reach a marble score of 2 or greater.

EU Index – Estimates the genetic differences between animals in net profitability per cow joined for an example commercial herd targeting pasture finished steers for the EU market. Steers are assumed marketed at 620kg live weight (340kg HSCW and 14mm P8 fat depth) at 24 months of age. Daughters are retained for breeding. There is no marbling requirement.

Hereford Selection Indexes make bull buying easier. They take the hard work out of knowing how much emphasis you should give to each of the available EBVs when selecting a replacement sire by weighting the available EBVs according to their impact on the long-term profitability of your herd, balancing fertility and maternal traits with growth and carcass traits. The index is in fact

a multi-trait EBV that estimates the relative value of each animal to your chosen market goal – reflecting the extra earning capacity per cow joined in a self replacing commercial herd.

Animals can be compared using Selections Index values in the same manner as comparing them using EBVs for single traits, but instead of looking at a large number of EBVs (up to 18) the first screening at least, can be on the single index value. You may then fine tune the match with your herd by considering individual EBVs.

Typical production statistics, prices and costs underlie each Index. Each index has subtly different input statistics appropriate to the market end-point, eg. age and weight at sale, marbling etc.

Benefits and costs evaluated include both those for the long-term sustainability of the cow herd and those for the sale animal from birth to slaughter. Essential compromises between traits such as the flow-on effects of increased growth on birth-weight & cow maintenance are accounted for when calculating indexes.

In pasture phases, feed is assumed to be a limiting factor for part of the year, and that any increase in feed requirement at herd level is a cost. The assumed herd calving rate and level of calving difficulty each reflect a moderate level of concern that these traits not change unfavourably from the selection of new sires.

Animals will have selection indexes reported only if sufficient information has been recorded for them. Specifically, an animal must have:

- performance recorded with BREEDPLAN or progeny with performance recorded
- one of the birth EBVs (B.Wt, CED) with an accuracy of 40% or higher
- one of the growth EBVs (200, 400, 600) with an accuracy of 40% or higher
- one of the scan or carcass EBVs (EMA, IMF, Fat Depth) with an accuracy of 40% or higher
- one of the fertility EBVs (DTC, SS, CEDtrs) with an accuracy of 30% or higher

Selection index values will not be reported for animals that do not meet these criteria.
